"Can We Afforda Revolution in Military Affairs?" Cindy Williams and Jennifer M. Lind

Breakthroughs (Spring1999), pp. 3-8

The Department of Defense and a wide array of scholars, analysts, and visionaries outside the military assert that the U.S. military is on the threshold of a revolution in military affairs (RMA). The revolution, sparked by rapid advances in information technologies and information processing capabilities, has the potential to transform the essential elements of the armed forces, favoring them with a decisive advantage in future warfare. Proposals abound for exploiting this revolution to ensure that the United States secures the benefits for its military and denies them to potential adversaries.[1]

Little has been said, however, about the long-term affordability of these proposals. How much will it cost to exploit a revolution? Where will the money come from? Of course, it is impossible to answer either of these questions with any rigor. Specific proposals for exploiting the revolution vary widely, and some of the more futuristic suggestions do not lend themselves to the harsh reality of cost estimation. And future defense budgets are difficult to predict with any accuracy. Yet an examination of just a few of the proposals on the table shows that capitalizing on the so-called revolution could add tens of billions of dollars to annual defense budgets a decade from now. Moreover, despite projections of huge and growing federal budget surpluses, finding the additional money will not be easy.

How Much Will It Cost?

Inside and outside the U.S. military, much of the discussion of a revolution in military affairs centers on the exploitation of information technologies to achieve information superiority on and off the battlefield. The technologies that underlie the so-called revolution are those related to command, control, communications, intelligence (C3I) and information. The prevailing view is that these technologies are cheap compared to the major weapon platforms that they support, and that they will be even cheaper as the military capitalizes increasingly on commercial off-the-shelf systems (COTS).

The truth is that these technologies, taken as a group, are not cheap. The Defense Department currently devotes 20 percent of its budget — up from 15 percent in 1985 — to C3Iand information systems. Spending for these areas comes to about \$54 billion in the fiscal year 2000 budget that President Clinton submitted to Congressing January 1999.[2] And the migration to COTS is not saving as much money as proponents once hoped. Using COTS lowers the price of individual components and software, but it raises problems of hardware and software integration and replacement cycles for which the government still finds it difficult to plan.

\$54 billion a year is a lot of money by anybody's standards. It exceeds the entire defense budget of every country in the world with the exception of the United States and Russia. It is just \$10 billion lower than Russia's total budget for defense.[3] At this price, if a

revolution has not already occurred and been exploited to the fullest, then somebody ought to ask why not.

To be fair, not all of that money can be attributed to exploiting a revolution in military affairs. A good deal of it supports Cold War legacy programs that RMA supporters would call part of the problem rather than part of the solution. But it does pay for the information superiority that supporters say is the backbone of the revolution.

How much more would the U.S. military need to spend to exploit the revolution that advocates posit? It is not easy to determine an amount, in large part because the changes that people have in mind are far from well defined.

Advocates argue that much of the transformation they seek will come from changes in doctrine, operational concepts, organization, and training rather than through specific technologies or systems. They assert that a good deal of the technology needed is already at hand; exploiting it requires changes in culture and attitude more than additional investment in equipment.

It is difficult to estimate the costs of transforming culture and attitude. The Pentagon's advanced warfighting experiments and advanced concept technology demonstrations are aimed at exploring new operational concepts and changes in doctrine. The Defense Department will spend less than \$1.5 billion a year on them through 2005.[4] If these experiments and demonstrations represent the main path to transforming the culture, then transformation is relatively cheap and already covered in the Pentagon's budget plans.

But, despite the lip service paid to cultural and doctrinal change, the transformation that many RMA advocates seek rests on a base of technology and systems. The Pentagon asserts that its current plans already support a transformation of the military by funding information technologies as well as a number of "leap-ahead" enabling technologies. Nothing needs to be added to exploit the RMA.[5] But to outside advocates, the technologies that the Pentagonites as "leap-ahead" — the Comanche helicopter, the New Attack Submarine, the F-18 E/F and F-22 fighters — are just incremental improvements to Cold War systems. Real exploitation calls for significant additional investment.

Proposals for new systems run the gamut from the familiar to the completely new. Some of the more familiar concepts include precision guided munitions, new mobile vehicles to conduct more integrated C3I operations, and a battle management aircraft that would combine features of the Joint STARS ground tracking plane and the AWACS airborne warning and control system. Other ideas would add weapons to platforms that today are used for communications or sensing rather thanas combat vehicles: unmanned aerial vehicles outfitted with conventional weapons, projectile weapons based in space. Still other proposals offer concepts that would be quite new to military arsenals, for example trans-atmospheric vehicles that carry precision guided munitions, combat vehicles that require no fuel or ammunition, directed energy weapons launched from platforms not yet invented, infrasonic weapons, and computer viruses used as weapons.[6]

Estimating the costs of items in the last category is a tricky business. The best cost estimates for a new system are based on a clear understanding of the system's design. They often incorporate comparisons with similar systems that have been purchased or at least attempted in the past. For the more futuristic concepts, the designs and their analogs for comparison are difficult to come by.

Cost estimates for types of systems with which the military already has some design experience are more feasible. For example, one RMA supporter recommends that the military explore technologies for precision weapons, smaller and more mobile computers and communications systems, information warfare, stealth, unmanned vehicles and robots, and space-based systems, including weapons in space.[7] Technologies on this list lend themselves to cost estimation, using analogs like the canceled Brilliant Pebbles program that would have put weapons into space under President Reagan's Strategic Defense Initiative.

The author of that list urges boosting research and development spending by \$100 billion over the coming decade to explore the technologies on the list. That \$10 billion year would be a major increase over the \$34 billion that the Pentagon currently plans to spend on R&D in the coming decade. It would indeed pay for significant levels of technology exploration. But to assume that none of this exploration will lead to engineering and manufacturing development and then to procurement would be completely disingenuous. And as programs mature beyond the exploration phase, their costs rise. If just one program in each of those areas makes it into engineering and manufacturing development and then production, costs could rise an additional \$15 billion a year by 2010. Moreover, operating and support costs for the new systems will be far from free.

In short, it is hard to pin a specific price tag on exploiting a revolution in military affairs. The Pentagon would have us believe that it is virtually free, that is, already included in its planned programs. One recommendation offered by an advocate outside the military calls for \$10 billion a year above current Pentagon plans, but focuses on exploratory research and development. Overtime, programs that grow out of that exploration could add another \$15billion a year in acquisition and more for operation and support. Thus, conservative estimate for a sustained program of technology exploration and force modernization based on just a few of the new technologies comes to \$25 billion a year by the end of the next decade.

Where Will the Money Come From?

The Defense Department's most recent budget comes to \$263 billion in fiscal year 1999 and even higher amounts later in the decade. At first blush, it would seem that the Department could pay for any transformation it wants out of that amount of money.

But the truth is that defense dollars do not go as far as they used to. On the acquisition side, weapons costs continue to grow, both from generation to generation and from initial estimates to actuals. The F-22 fighter will cost at least twice as much per airplane as the F-15 that it replaces and 20 percent more than the Air Force currently admits.[8]

On the support side, per-troop spending for operation and maintenance has grown in real terms by an average of more than three percent a year over the past 25 years. O&M now eats up more than 37 percent of the Defense Department's budget, compared with28 percent in the mid-1980s. [9]

The Clinton Administration instituted a major round of procurement reform and several initiatives aimed at bringing the Department's operating and maintenance costs under control. These efforts have failed to achieve the promised savings.[10] New weapons cost increases are on the way, and O&M spending will shoot to 39 percent of the budget for fiscal year 2000. The upshot is that retaining the current force structure at current levels of readiness, and equipping it as the Defense Department currently plans, will cost as much as \$40billion more each year in the coming decade than we are paying today.[11]

It is possible that Americans will be willing to pay that much. Projections of the U.S. federal budget surplus are huge — \$107 billion this year and more than \$350 billion by 2009.[12] But that surplus depends on continued favorable conditions in the economy and on adhering to the spending limits spelled out in the1997 balanced budget agreement — limits that would hold defense spending for several years at about last year's level in real terms.

Also, defense is only one of the claimants for the surplus. Social Security, Medicare, and tax cuts are all potential beneficiaries of the windfall. And with baby boomer retirements starting around 2010, pension and health care programs may dominate priorities for the marginal federal dollar in the coming decade.

If Americans are not willing to boost defense spending significantly, then the gap between plans and money will have to be closed the other way by reducing defense expectations. The main choices for reducing defense plans can be grouped into four categories: reprioritize and reduce existing programs in the areas of C3I and information technologies, constrain other modernization plans, slice military force structure, or cut back on military infrastructure.

The Pentagon has tried for several years to get the owners and acquisition agents of socalled "legacy" command and control systems to migrate to newer systems. The legacy systems, some in operation and some still being acquired, were conceived during the Cold War. Many of them were designed in what the military refers to as a "stove-pipe" fashion to handle a single function within a single military service or command. As a result, there are numerous systems, and their functions often overlap. Moreover, some of them are quite cumbersome to use. Since they were designed years ago, the technology that they incorporate generally not up to date.

Migrating to newer, joint systems would cut the costs of operating and building multiple systems with overlapping functions and could free up some of the money that advocates of transformation would like to see spent on new technologies. But pulling the plug on legacy systems that support critical ongoing functions when the new systems are not

ready has not been easy. Until new systems are in-hand and working, the military has little choice but to continue using the old ones.

Some advocates of revolution have suggested that the money to pay for change should be taken from the Pentagon's ongoing modernization programs. They argue that most of these programs are left over from the Cold War and represent yesterday's technology rather than tomorrows.

The most lucrative single modernization cutback would come from canceling all three of the military's new fighter aircraft programs: The Air Force F-22, the NavyF-18E/F, and the multi-service Joint Strike Fighter. The combined procurement costs of those three programs will be about \$12 billion annually over the next two decades. But the fighter airplanes in the force structure today are rapidly reaching the end of their useful service lives. Unless the United States is ready to go without fighter aircraft altogether, canceling the three programs would require adding new funds to extend the service lives of existing planes or to build new ones using existing production lines. Either choice would eat into the savings achieved through cancellations.[13] As a result, the net annual savings achieved by canceling all three new airplanes might be between \$4 billion and \$6 billion.

Other expensive modernization targets include the Marine Corps' V-22 transport plane, the Navy's New Attack Submarine, or the Army's Comanche reconnaissance and attack helicopter systems that the Pentagon classes as "leap-ahead" but that were largely conceived during the Cold War. Canceling any of these systems would free up money for new programs, but as with the fighter programs, the savings would be significantly offset by efforts to extend the lives of the systems that they are intended to replace.

Fitting new procurement programs into the defense budget when the Pentagon's purchasing accounts are already squeezed is not easy. The fiscal year 2000 budget for all of the military's weapons purchases comes to \$53 billion. In contrast, the procurement bill for the modernization scheme that the Defense Department has already embarked on comes to more than \$70 billion a year during the next decade. The Defense Department wants to boost spending for procurement significantly in the coming years. But its hopes for future procurement increases have been dashed time and time again in recent years as it has confronted its must-pay bills for operation and maintenance.

Some proponents of revolution argue that the right combination of air power, precision munitions and information superiority will be so effective by themselves that the United States can significantly reduce its force structure — particularly Army force structure — thereby saving billions of dollars a year. They may be right. But significant sums will not be saved without massive force structure cuts and wholesale reorganization. For example, eliminating thereof the Army's ten active-duty divisions would save only \$4 billion a year in direct and indirect costs — far short of the \$10 billion that one Marooning would like to add to R&D just to get things started.[14]Saving more would require significant cutbacks in the so-called institutional Army — the schools and other

parts of the Army that would not deploy in wartime. And of course, those savings and much more may be needed just to stay within likely defense budgets.

The final alternative for reducing defense plans is to cut back on military infrastructure. Examples that have been examined by the Pentagon or others include closing an additional50 military bases; closing most of the military's hospitals and providing military families with access to the health insurance program that covers government civilians; eliminating the family housing at military base sin the United States and supplementing the troops' housing allowance to make private-sector rents affordable; or dropping the taxpayer's subsidy to military grocery stores in the U.S.[15] Taken together, these changes might save \$5 billion to \$6 billion a year. But each of them is extremely unpopular with some sector: communities that might lose the bases or hospitals, advocates for military families and retirees, and to some extent the Congress.

One thing is certain: The Administration's plan for trimming at the edges of military infrastructure by outsourcing routine jobs like handling the military payroll or clipping the grass on military bases has not yielded the promised savings. To save money on military infrastructure other than through base closures, the Defense Department will have to cut back significantly on services and functions that it is reluctant to part with.

Summary and Conclusion

It appears that transforming the military to capitalize on any revolution in military affairs will be affordable only if American attitudes toward defense spending in the post-Cold War period undergo a sea change, or if the wholesale downsizing of the military and its modernization programs continues through the next decade.

The U.S. military already spends a significant portion of its budget on the technologies and programs that support information superiority. Some advocates of exploiting a Raoul like to add more to explore new technologies. The extra annual acquisition costs incurred if just a few of those technologies lead to procurement programs could exceed \$25 billion. Operating costs will add to the budget pressures. Given that the current defense program already faces a potential shortfall in the neighborhood of \$40 billion a year, any new RMA-related project will face formidable competition for funds.

Money for new programs could come from adding to the defense budget, reprioritizing within theC3I category or reducing other defense programs. Despite large projected surpluses in the federal budget, freeing up new money for defense will be difficult. Even if additional money is poured into defense, it will likely be consumed just to maintain the status quo and shore up the widening gap between the Defense Department's hopes and its likely budgets. Taking the money from infrastructure or from Cold War C3I programs makes good sense, but has been difficult for the Pentagon to carry out. That leaves tradeoffs against force structure and other modernization programs Absolution that appeals to advocates of change but is frightening to the Services, which are deeply concerned at the prospect of giving up forces or modernization programs in exchange for

unproven technologies.

ABSTRACT

Cindy Williams

PAYING FOR THE RMA

The U.S. Department of Defense and a wide array of scholars, analysts, and visionaries outside the military assert that the U.S. military is on the threshold of a revolution in military affairs (RMA). The revolution, sparked by rapid advances in information technologies and information processing capabilities, is said to have the potential to transform the essential elements of the armed forces, favoring them with a decisive advantage in future warfare. Proposals abound for exploiting this revolution to secure its benefits and deny them to potential adversaries. Little has been said, however, about the long-term affordability of such proposals.

The United States currently spends more than \$60 billion of its nearly \$400 billion annual military budget on command, control, communications, intelligence (C3I), and information systems--the technologies and programs that support information superiority. Although this is more than any other nation in the world spends in to toon its military, some U.S. advocates of exploiting the RMA would like toad more to explore new technologies. The extra annual acquisition costs that will be incurred if just a few of those technologies lead to procurement programs could exceed \$30 billion. Operating and maintaining any new systems will also add to the costs.

Money for new programs could come from adding to the defense budget, reprioritizing within theC3I and information systems categories, or reducing other defense programs. As President Bush's budget plan for the 2003 fiscal year shows, however, even when additional money is poured into defense, it is typically consumed just to maintain the status quo, rather than to spur the kind of innovations that a revolution in military affairs would entail. Taking the money from infrastructure or from Cold War C3I programs makes good sense, but has been difficult in the past for the Pentagon to carry out. That leaves tradeoffs against current force structure and other modernization programs--a solution that appeals to advocates of change but is frightening to U.S. military services, which are deeply concerned at the prospect of giving up forces or procurement programs in exchange for unproven technologies.

REWARDING AND MANAGINGALL-VOLUNTEER MILITARIES IN THE INFORMATION AGE

MIT Security Studies Program

Modern militaries face deep contradictions between the thriving, competitive, modern marketplaces in which their uniformed forces must compete for volunteer members and

the centuries-old traditions and systems that they generally rely upon to reward and manage them. Today's militaries must compete for network specialists and information engineers who are just as qualified as those who work for technology firms in the global economy. They must also hire and hold onto a pool of less skilled workers who will find satisfying careers in less challenging areas. Yet some countries, including the United States, try to accomplish both goals with a one-size-fits-all system of pay and benefits that rewards people based on rank, years of service, and family status, rather than on skill or performance. Except in a few categories of expertise, the systems allow little flexibility in the rank at which members enter service or the pay they receive.

A growing number of countries are now acquiring experience with non-conscript forces. Britain abolished the draft during the 1960s. The United States followed in the1970s. Western European nations are moving increasingly toward all-volunteer forces. During the past five years, Belgium, the Netherlands, and France have abolished conscription; Italy's parliament voted in October 2000 to move to an all-professional force. German leaders continue to see conscriptions a positive force in East-West integration, but Germany may still adopt an all-professional force in the future. Outside Europe, Australia, Japan, Canada, and India have all-volunteer forces.

Analysts and policymakers in some countries are exploring the benefits and feasibility of adopting more flexible reward structures, embracing more flexible entry policies (perhaps allowing people with special skills or training to join the military at higher ranks), and making other changes in personnel policies to improve the armed forces' ability to recruit, retain, and manage skilled and qualified cadres in the information age. This lecture will examine variety of innovative approaches to such challenges.

THE BUSH DEFENSE BUDGET

In with the Old in 2003

By Cindy Williams

Cindy Williams is a principal research scientist in the Security Studies Program at the Massachusetts Institute of Technology and a former assistant director of the Congressional Budget Office.

February 3, 2002

IN HIS STATE OF THE Union address on Tuesday, President George W. Bush said winning the war against terrorism and protecting the homeland are the top priorities of the 2003 budget he will send to Congress tomorrow. The sheer size of the increase he proposes for national defense, \$48 billion above last year's level of \$343 billion, clearly reflects the sense of urgency and importance Americans attach to national security since the awful events of Sept. 11.

The special demands of the war on terrorism make it more important than ever that leaders make sound choices about the nation's defense. The president's planned rise reflects a deep and unsettling problem, however: The administration has failed to set priorities and make important choices about the structure and equipment of future U.S. military forces. As a result, the Bush plan will waste substantial sums on forces and weapon systems that served the nation well during the Cold War but make little sense for the operations our military faces today and in the future.

From a financial point of view, next year's increase is only the tip off the iceberg. If Congress accepts the administration's plan, then defense costs will mount rapidly in future years as the bills to sustain the forces and purchase new weapons accumulate. Moreover, failing to reshape our military for the world we actually live in will dilute the military's ability to focus on the grave concerns that face the nation, a consequence far more troubling than the financial costs.

Secretary of Defense Donald Rumsfeld planted the seeds for the large increase with the Quadrennial Defense Review he delivered to Congress last October. The review, required by law in the first year of each presidential term, is supposed to describe the national- security environment, outline the administration's national defense strategy and lay out plans for military forces, equipment and budgets consistent with the strategy. While Rumsfeld's review rightly recognized that we live in a new world and that U.S. defense strategy must change dramatically, it reflected none of the hard choices about forces and weapons that are needed to reshape the military to deal with today's problems. Instead of the detailed blueprint for a new house, the review became an advisory notice that the old house faced imminent danger from earthquakes, together with an artist's sketch of a modern but unattached kitchen.

For example, the Quadrennial Defense Review established homeland defense, rather than fighting wars overseas, as the top priority of U.S. military forces. Yet it offered no changes in forces to turn that new vision into reality. The National Guard and Reserves are playing a crucial role in homeland security, with Guardsmen helping to protect U.S. airports, airspace and borders. Nevertheless, the review did not recommend reducing the Guard 'scold War role in large-scale combat overseas - a role that conflicts with the homeland defense mission that must now take precedence.

In another example, the report stressed the danger of "asymmetric threats"- low-tech, relatively inexpensive methods of attack that terrorist groups or poor nations can use while avoiding direct confrontation in large-scale conventional battles. The terrorist attack on the U.S.S. Cole in 2000 was a vivid reminder that surface ships are vulnerable to threats as simple as a motor boat loaded with explosives. Yet the Rumsfeld review fell short of recommending adjustments to the Navy's Cold War balance between surface ships and more survivable submarines.

Similarly, the report placed new emphasis on readying forces to fighting foreign locations where access to bases, ports and airfields is difficult to come by. As the report presaged, Washington had difficulty in October persuading Afghanistan's neighbors to permit U.S. planes to fly combat missions from their territory. Yet the Defense Department made no plans to reshape forces to rely less on short-range, land-based aircraft and more on long-range bombers or aircraft carriers.

Finally, the Quadrennial Defense Review called for military transformation. Transforming the military into lighter, more agile, more mobile and more lethal forces that capitalize on modern technologies such as robotics and information systems was a lynchpin of the Bush presidential campaign. Yet the Quadrennial Defense Review's approach watered the original concept down to look more like inching toward change. And the review made clear that if any innovative systems were to be added, at least for the time being they would come on top of existing plans; it did not name a single weapon system to be canceled or slowed.

Thus, the review kept all three fighter airplane programs - F-22, F-35joint Strike Fighter, and F-18 E/F - singled out by President Bush on the campaign trail as an example of the Clinton administration's failure to make tough choices. Even the Army's Crusader self-propelled artillery system, technically advanced and uniquely capable but ill-suited for likely future fights, and the Marine Corps' V-22, plagued by technical problems and accidents, remained on the shopping list.

Reforming large institutions to cope with new environments requires shedding the old as well as adding the new. For the Defense Department, keeping the old when it is no longer relevant means continuing to battle entrenched interests in the armed services, defense industry and Congress. Only by giving up forces and systems that no longer make sense can the nation make way for change in the military.

Some people argue that keeping everything is a good idea; in uncertainties, you never know what you may need. Aircraft carriers played a crucial role in the war in Afghanistan; the Army will need heavy armored divisions if we go to war against Iraq; Air Force fighter planes are now essential to homeland security. Their examples do illuminate the importance of keeping wide array of forces; nobody ever argued seriously that we should not. But those arguments have no bearing on the technical complexity required; an F-16 is better suited to flying combat air patrols looking for stray commercial aircraft than an F-22, and a lot less expensive. Nor do they shed any light on the number of units we need.

In light of the tragic events of last September, Americans may be happy to pay this year's dollar price of keeping everything and deferring hard choices. Unless taxes go back up, however, mounting defense bills in future years will cut deeply into the much-reduced federal surplus the Congressional Budget Office now projects for the coming decade, thus eroding the prospects for Social Security and Medicare just as the baby boom generation approaches retirement age. If those sacrifices are what it takes to achieve security for this country, then Americans will make them. But we should not be asked to make such sacrifices for slack defense management.

More troubling than the financial costs is the potential effect on the military itself if priorities are not set and forces are not reshaped to deal with the nation's most pressing challenges. Training for unlikely missions diverts soldiers from preparing for the likely ones; building unneeded weapons ties up military procurement managers whose talents are urgently needed elsewhere. The effects on military capability and morale may greatly exceed the financial costs. Only by setting priorities and making the sorts of tough choices President Bush promised on the campaign trail can the nation come anywhere near achieving the military for the world we now live in.
